Requirements Elicitation Report

1. List of Requirements

In this section you are expected to provide requirements covering the proposed functionality of your software (including functionality, users and non-functional aspects of your system).

You are expected to explain each requirement clearly with identifying type of requirement. For functional requirements (RQs), specify the ones that describe data requirements using a “D” as it is depicted in RQ 1. You are expected provide at least 40 functional RQs. For non-functional RQs identify the type of it such as usability, platform or security as depicted in RQ 2. You are expected provide at least 10 non-functional RQs.

In the priority column, you need to declare if the given RQ is related to a core or an optional function. Core functions are the functions that you need to implement for your prototype to work and an optional function are the ones that you plan to implement if implementation stage goes as planned.

In the use case column, you need to identify which use-case(s) this RQ relates to. The use cases identified in the table must match the use cases from the diagram in the next section. (**Advice:** Fill this column after you complete your use case diagram)

ID	Requirement	Type	Priority	Use Case
1	Each customer must be identified with a unique username.	Functional (D)	Core	Login
2	Customers must be able purchase an item with max of 3 button clicks.	Non-functional Usability	Core	Buy item
3	Customers must be able to login with a username and password.	Functional	Optional	Login
4	The system must have two types of users: customer and admin.	Functional	Core	All
5	The system must run on Android and iOS mobile systems	Non-functional Platform	Core	-
6	The system must not allow performing customer and admin activities without authentication.	Non-functional Security	Core	-

2. Use-Case Diagram

In this section provide a use-case diagram showing associations between users and use cases.

3. Use Case Description

In this section, describe two of the key use cases from the diagram in the previous section. Only include the following information.

Name – The name of the use case, must match one of the use cases from the diagram.

Brief Description – A brief text describing the scope of the use case.

Actors – A list of the types of users who can engage in the activities described in the use case. Actor names should correspond to those in the diagram.

Preconditions – Anything the solution can assume to be true when the use case begins. For example, you can specify user log-in as a precondition.

Basic Flow – The set of steps the actors take to accomplish the goal of the use case. A clear description of what the system does in response to each user action.

Alternate Flows – Capture the less common user/system interactions, such as being on a new computer and answering a security question.

Post Conditions – Anything that must be true when the use case is complete

Use Case 1:

Search for consultant

This use case exists to find a consultant that they need to analyse or look at the details of, is available for a specific region or a consultant that has scheduled time for the specific task, but also to look for a specific consultant that you may want to find details for or other information about the consultant. The main actor for this use case is HR; they can search for Consultants for the Job they need to be completed. For this use case to be executed we assume HR has successfully logged into the portal and that consultants exist in the Employee portal database to be searched from. For the use case to return a useful value, we also assume that the information given by HR to search for the consultant is correct and exists in the database of consultants.

The flow for this use case is as follows, the HR user first select the field (employee name, ID number, Region etc) they want to search for the consultant with. Then they will input a detail into the Employee portal interface, the data inputted will then be used to search for all consultants that match that information in the field selected. The HR employee then needs to select the consultant from the list returned and shown to the HR employee on the Portal interface. An alternative to this sequence is when the HR employee inputs the data to search for the consultant with, that data does not exist in the field specified and no employee list is given. The portal will then prompt the HR employee to search for the employee with the same data in a different field. This then will repeat the primary and alternative flow sequence until a consultant is found and selected by the HR employee. When the use case is complete, an employee will be selected by the HR employee unless they back out of the search.

4. Risk Assessment

In this section, the group is expected to provide a risk assessment for their project. The risks must include project risks and health and safety risks. You are expected to identify at least 10 risks.

Risk	Likelihood	Severity	Impact	Preventative / Mitigating Actions
Poor time management	High	High	Unfinished product	Evaluate progress frequently and adjust project plan if necessary
Missing member(s) due to health issues	High	Medium	Unfinished/ low quality product	Have frequent meetings and communication to make sure all members aware of each other's progress.

How to perform risk analysis¹:

Step 1: Identify potential risks. Create a list of every possible risk. If you only focus on the threats, you could miss out on the chance to deliver unexpected value to the customer or client. Ask your team to help you brainstorm during the project planning process, since they might see possibilities that you don't.

You can find a list of possible risks in a project on this website². Do not just copy and paste risks from the list, identify the ones that apply to your project and use your own words to describe the risk.

Step 2: Determine probability. What are the odds a certain risk will occur? It's a lot more likely that a key team member will be out for a week with the flu than develop total amnesia. Rate each risk with high, medium, or low probability.

Step 3: Determine Impact. What would happen if each risk occurred? Would your final delivery date get pushed back? Would you go over budget? Identify which risks have the biggest effect on your project's outcomes, and rate them as high impact. Rate the rest as medium or low impact risks.

Step 4: Determine actions that might prevent/mitigate the risk³. If you can avoid a particular risk, then it makes sense to do so. However, that's not always possible, and there are some risks that just can't be avoided. When you're performing your initial risk assessments, identify ones that you can avoid.

Unfortunately, some risks can happen unexpectedly, and you won't be able to control them. In this case, you can only react to the situation. However, there are some risks that are much easier to keep in check.

You can plan well ahead and decide how you want to deal with them and install some contingencies. For example, if there's a high likelihood of fire in your project, you can work on ways to prevent the fire from happening from the very beginning. If the fire still occurs, you can have a plan to contain the damage and ensure that injuries and casualties are at a minimum.
